## Escapes in k8s - attack vectors

- Create necessary-evil containers and Pods
- Pod with dangerous configurations
- Container runtime vulnerabilities
- Kernel vulnerabilities
- k8s vulnerabilities
- In theory: hardware attacks - Exploiting Speculative Execution

# Что изменилось с того времени?

1. Kubernetes с версии 1.19 дошел до 1.31
2. Появился второй отчет стороннего аудита Kubernetes 1.24 (был для 1.13)
3. Отменена поддержка docker
4. Отменена поддержка PodSecurityPolicy (PSP)
5. Появился PodSecurity Admission (PSA)
6. Переходы feature-gates в другие стадии
7. Default seccomp стал GA
8. Появился Kubelet-in-UserNS (Rootless mode)
9. Появились Ephemeral Containers
10. Kubernetes CVE Feed
11. Kubernetes переходит Cgroup v1 на Cgroup v2
12. Появился UserNamespacesSupport
13. Forensic Container Checkpointing
14. Добавились ValidatingAdmissionPolicy и MutatingAdmissionPolicy
15. Поддержка AppArmor в stable
16. И так далее ...

# kCTF и kernelCTF

stephen  
@\_tsuro

We just announced a new bug bounty on a hardened kubernetes cluster.

The fun part: 1days are explicitly in scope!  
Want to exploit a public #syzkaller bug that hasn't been patched in our cluster yet? That's fair game.

More info here:

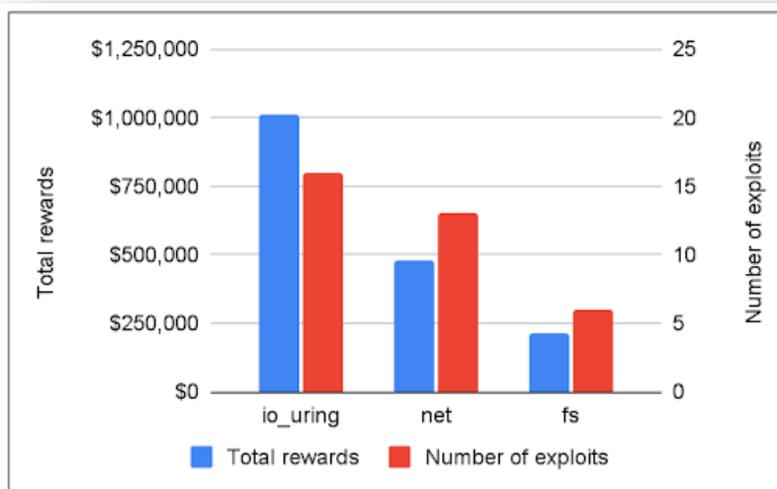

Expanding our work with the open source security community

## Introducing kernelCTF

To better align incentives with our areas of interest, we are shifting our focus from GKE and kCTF to the latest stable kernel and our mitigations. As a result, starting today we will handle kernel exploit submissions under a new name, "kernelCTF," with its own [reward structure and submission process](#). The maximum total payout for kernelCTF is still \$133,337 per submission. While the specific GKE *kernel* configuration is still covered by the new kernelCTF, exploits affecting non-kernel components like the full GKE stack (including Kubernetes), the container runtime, and GKE itself, are now separately eligible for vulnerability rewards under the kCTF VRP which is returning to its [original reward amounts and conditions](#).

# Root, capability's, namespaces, ...

История root пользователя и capability

БЕКОН

Вехи развития

- До версии Linux 2.2
  - До 1999 года
  - Пользователь root (UID 0) со всеми привилегиями
  - Остальные пользователи (UID не 0) без привилегий
- С версии Linux 2.2 до 3.8
  - Привилегии пользователя root разбиваются на capability
    - На пример, CAP\_NET\_ADMIN, CAP\_SYS\_ADMIN, CAP\_NET\_BIND\_SERVICE и т.д.
  - Capability можно забирать и выдавать
  - За capability по сути скрывается системный вызов с определёнными аргументами
- С версии Linux 3.8
  - С 2013 год
  - Появление user namespaces (UserNS) и деление на initial и unprivileged user namespaces
  - Capability перестали носить глобальный характер, а стали относиться к user namespaces
  - Появился Global root это root в initial user namespace

# unshare()

Creation of new namespaces using `clone(2)` and `unshare(2)` in most cases requires the `CAP_SYS_ADMIN` capability, since, in the new namespace, the creator will have the power to change global resources that are visible to other processes that are subsequently created in, or join the namespace. User namespaces are the exception: since Linux 3.8, no privilege is required to create a user namespace.

## `unshare(2)`

The `unshare(2)` system call moves the calling process to a new namespace. If the *flags* argument of the call specifies one or more of the `CLONE_NEW*` flags listed above, then new namespaces are created for each flag, and the calling process is made a member of those namespaces. (This system call also implements a number of features unrelated to namespaces.)

# Ooops!

Creation of new namespaces using `clone(2)` and `unshare(2)` in most cases requires the `CAP_SYS_ADMIN` capability, since, in the new namespace, the creator will have the power to change global resources that are visible to other processes that are subsequently created in, or join the namespace. User namespaces are the exception: since Linux 3.8, no privilege is required to create a user namespace.

# Пример: CVE-2022-0185

## CVE-2022-0185 Detail

### Description

A heap-based buffer overflow flaw was found in the way the `legacy_parse_param` function in the Filesystem Context functionality of the Linux kernel verified the supplied parameters length. An unprivileged (in case of unprivileged user namespaces enabled, otherwise needs namespaced CAP\_SYS\_ADMIN privilege) local user able to open a filesystem that does not support the Filesystem Context API (and thus fallbacks to legacy handling) could use this flaw to escalate their privileges on the system.

### Metrics

CVSS Version 4.0

CVSS Version 3.x

CVSS Version 2.0

NVD enrichment efforts reference publicly available information to associate vector strings. CVSS information contributed by other sources is also displayed.

#### CVSS 3.x Severity and Vector Strings:

NIST: NVD

Base Score: **8.4 HIGH**

Vector: CVSS:3.1/AV:L/AC:L/PR:N/UI:N/S:U/C:H/I:H/A:H

This bug popped up since **5.1-rc1**. It's important to note that you need the `CAP_SYS_ADMIN` capability to trigger it, but the permission only **needs to be granted in the CURRENT NAMESPACE**. Most unprivileged users can just `unshare(CLONE_NEWNS | CLONE_NEWUSER)` (equivalent of the command `unshare -Urm`) to enter a namespace with the `CAP_SYS_ADMIN` permission, and abuse the bug from there; this is what makes this such a dangerous vulnerability.

# kernelCTF

Уменьшение выплат при использовании unprivileged user namespaces.

## Reward

- \$21.000 if the exploit does not use user namespaces and io\_uring
- \$10.500 if the exploit uses user namespaces or io\_uring
  - This reward is based on whether the exploit works on GKE AutoPilot or not. AutoPilot currently does not enable unprivileged user namespaces and they are also considering disabling io\_uring.

- Reduced attack surface bonus (+\$20.000)
  - Criteria: Exploit works without using unprivileged user namespaces.

# Защита от unshare() и kernel exploits

1. Использование Default seccomp profile на kubelet
  - Известно также как SeccompDefault и RuntimeDefault.
  - Некоторые компоненты не смогут подняться (на пример, CNI)
2. Mutation webhook с SeccompDefault профилем
  - Сначала тесты в режиме аудита, потом в режиме блокировки
3. Mutation webhook с custom seccomp профилем
  - Очень долго и сложно из-за большого количества тестов
4. SeLinux профиль
  - Только для RedHat based OS
5. Усложнение запуска эксплоита с помощью AppArmor профиля
  - Только Debian based OS
  - Нужно создать профиль под каждый контейнер
6. Следование принципу наименьших привилегий
  - Rootless контейнеры, distroless образы, container specific OS для хоста
7. Установка обновлений для ядра
  - Обязательно, но это долго и требует перезапуск Nodes кластера
8. Альтернативные runtimes на базе sandbox, виртуализации
  - На пример, gVisor, Kata containers.
  - Замедляют работу кластера, не каждая нагрузка запустится, добавляют точку отказа, теряется observability

# CVE B runc

## Search Results

There are 20 CVE Records that match your search.

Name	Description
<a href="#">CVE-2024-3154</a>	A flaw was found in cri-o, where an arbitrary systemd property can be injected via a Pod annotation. Any user who can create a pod with an arbitrary annotation may perform an arbitrary action on the host system.
<a href="#">CVE-2024-21626</a>	runc is a CLI tool for spawning and running containers on Linux according to the OCI specification. In runc 1.1.11 and earlier, due to an internal file descriptor leak, an attacker could cause a newly-spawned container process (from runc exec) to have a working directory in the host filesystem namespace, allowing for a container escape by giving access to the host filesystem ("attack 2"). The same attack could be used by a malicious image to allow a container process to gain access to the host filesystem through runc run ("attack 1"). Variants of attacks 1 and 2 could be also used to overwrite semi-arbitrary host binaries, allowing for complete container escapes ("attack 3a" and "attack 3b"). runc 1.1.12 includes patches for this issue.
<a href="#">CVE-2023-28642</a>	runc is a CLI tool for spawning and running containers according to the OCI specification. It was found that AppArmor can be bypassed when <code>/proc</code> inside the container is symlinked with a specific mount configuration. This issue has been fixed in runc version 1.1.5, by prohibiting symlinked <code>/proc</code> . See PR #3785 for details. Users are advised to upgrade. Users unable to upgrade should avoid using an untrusted container image.
<a href="#">CVE-2023-27561</a>	runc through 1.1.4 has Incorrect Access Control leading to Escalation of Privileges, related to libcontainer/rootfs_linux.go. To exploit this, an attacker must be able to spawn two containers with custom volume-mount configurations, and be able to run custom images. NOTE: this issue exists because of a CVE-2019-19921 regression.
<a href="#">CVE-2023-25809</a>	runc is a CLI tool for spawning and running containers according to the OCI specification. In affected versions it was found that rootless runc makes <code>/sys/fs/cgroup</code> writable in following conditions: 1. when runc is executed inside the user namespace, and the <code>config.json</code> does not specify the cgroup namespace to be unshared (e.g., <code>(docker podman nerdctl) run --cgroupns=host</code> , with Rootless Docker/Podman/nerdctl) or 2. when runc is executed outside the user namespace, and <code>/sys</code> is mounted with <code>rbind, ro</code> (e.g., <code>runc spec --rootless</code> ; this condition is very rare). A container may gain the write access to user-owned cgroup hierarchy <code>/sys/fs/cgroup/user.slice/...</code> on the host. Other users's cgroup hierarchies are not affected. Users are advised to upgrade to version 1.1.5. Users unable to upgrade may unshare the cgroup namespace ( <code>(docker podman nerdctl) run --cgroupns=private</code> ). This is the default behavior of Docker/Podman/nerdctl on cgroup v2 hosts, or add <code>/sys/fs/cgroup</code> to <code>maskedPaths</code> .
<a href="#">CVE-2022-29162</a>	runc is a CLI tool for spawning and running containers on Linux according to the OCI specification. A bug was found in runc prior to version 1.1.2 where <code>runc exec --cap</code> created processes with non-empty inheritable Linux process capabilities, creating an atypical Linux environment and enabling programs with inheritable file capabilities to elevate those capabilities to the permitted set during <code>execve(2)</code> . This bug did not affect the container security sandbox as the inheritable set never contained more capabilities than were included in the container's bounding set. This bug has been fixed in runc 1.1.2. This fix changes <code>runc exec --cap</code> behavior such that the additional capabilities granted to the process being executed (as specified via <code>--cap</code> arguments) do not include inheritable capabilities. In addition, <code>runc spec</code> is changed to not set any inheritable capabilities in the created example OCI spec ( <code>config.json</code> ) file.
<a href="#">CVE-2022-24769</a>	Moby is an open-source project created by Docker to enable and accelerate software containerization. A bug was found in Moby (Docker Engine) prior to version 20.10.14 where containers were incorrectly started with non-empty inheritable Linux process capabilities, creating an atypical Linux environment and enabling programs with inheritable file capabilities to elevate those capabilities to the permitted set during <code>execve(2)</code> . Normally, when executable programs have specified permitted file capabilities, otherwise unprivileged users and processes can execute those programs and gain the specified file capabilities up to the bounding set. Due to this bug, containers which included executable programs with inheritable file capabilities allowed otherwise unprivileged users and processes to additionally gain these inheritable file capabilities up to the container's bounding set. Containers which use Linux users and groups to perform privilege separation inside the container are most directly impacted. This bug did not affect the container security sandbox as the inheritable set never contained more capabilities than were included in the container's bounding set. This bug has been fixed in Moby (Docker Engine) 20.10.14. Running containers should be stopped, deleted, and recreated for the inheritable capabilities to be reset. This fix changes Moby (Docker Engine) behavior such that containers are started with a more typical Linux environment. As a workaround, the entry point of a container can be modified to use a utility like <code>capsh(1)</code> to drop inheritable capabilities prior to the primary process starting.
<a href="#">CVE-2021-43784</a>	runc is a CLI tool for spawning and running containers on Linux according to the OCI specification. In runc, netlink is used internally as a serialization system for specifying the relevant container configuration to the <code>C</code> portion of the code (responsible for the based namespace setup of containers). In all versions of runc prior to 1.0.3, the encoder did not handle the possibility of an integer overflow in the 16-bit length field for the byte array attribute type, meaning that a large enough malicious byte array attribute could result in the length overflowing and the attribute contents being parsed as netlink messages for container configuration. This vulnerability requires the attacker to have some control over the configuration of the container and would allow the attacker to bypass the namespace restrictions of the container by simply adding their own netlink payload which disables all namespaces. The main users impacted are those who allow untrusted images with untrusted configurations to run on their machines (such as with shared cloud infrastructure). runc version 1.0.3 contains a fix for this bug. As a workaround, one may try disallowing untrusted namespace paths from your container. It should be noted that untrusted namespace paths would allow the attacker to disable namespace protections entirely even in the absence of this bug.
<a href="#">CVE-2021-30465</a>	runc before 1.0.0-rc95 allows a Container Filesystem Breakout via Directory Traversal. To exploit the vulnerability, an attacker must be able to create multiple containers with a fairly specific mount configuration. The problem occurs via a symlink-exchange attack that relies on a race condition.
<a href="#">CVE-2021-20182</a>	A privilege escalation flaw was found in openshift4/ose-docker-builder. The build container runs with high privileges using a chrooted environment instead of runc. If an attacker can gain access to this build container, they can potentially utilize the raw devices of the underlying node, such as the network and storage devices, to at least escalate their privileges to that of the cluster admin. The highest threat from this vulnerability is to data confidentiality and integrity as well as system availability.
<a href="#">CVE-2020-14300</a>	The docker packages version docker-1.13.1-108.git4ef4b30.el7 as released for Red Hat Enterprise Linux 7 Extras via RHBA-2020:0053 ( <a href="https://access.redhat.com/errata/RHBA-2020:0053">https://access.redhat.com/errata/RHBA-2020:0053</a> ) included an incorrect version of runc that was missing multiple bug and security fixes. One of the fixes regressed in that update was the fix for CVE-2016-9962, that was previously corrected in the docker packages in Red Hat Enterprise Linux 7 Extras via RHSA-2017:0116 ( <a href="https://access.redhat.com/errata/RHSA-2017:0116">https://access.redhat.com/errata/RHSA-2017:0116</a> ). The CVE-2020-14300 was assigned to this security regression and it is specific to the docker packages produced by Red Hat. The original issue - CVE-2016-9962 - could possibly allow a process inside container to compromise a process entering container namespace and execute arbitrary code outside of the container. This could lead to compromise of the container host or other containers running on the same container host. This issue only affects a single version of Docker, 1.13.1-108.git4ef4b30, shipped in Red Hat Enterprise Linux 7. Both earlier and later versions are not affected.
<a href="#">CVE-2020-14298</a>	The version of docker as released for Red Hat Enterprise Linux 7 Extras via RHBA-2020:0053 advisory included an incorrect version of runc missing the fix for CVE-2019-5736, which was previously fixed via RHSA-2019:0304. This issue could allow a malicious or compromised container to compromise the container host and other containers running on the same host. This issue only affects docker version 1.13.1-108.git4ef4b30.el7, shipped in Red Hat Enterprise Linux 7 Extras. Both earlier and later versions are not affected.
<a href="#">CVE-2019-5736</a>	runc through 1.0-rc6, as used in Docker before 18.09.2 and other products, allows attackers to overwrite the host runc binary (and consequently obtain host root access) by leveraging the ability to execute a command as root within one of these types of containers: (1) a new container with an attacker-controlled image, or (2) an existing container, to which the attacker previously had write access, that can be attached with <code>docker exec</code> . This occurs because of file-descriptor mishandling, related to <code>/proc/self/exe</code> .
<a href="#">CVE-2019-19921</a>	runc through 1.0.0-rc9 has Incorrect Access Control leading to Escalation of Privileges, related to libcontainer/rootfs_linux.go. To exploit this, an attacker must be able to spawn two containers with custom volume-mount configurations, and be able to run custom images. (This vulnerability does not affect Docker due to an implementation detail that happens to block the attack.)
<a href="#">CVE-2019-16884</a>	runc through 1.0.0-rc8, as used in Docker through 19.03.2-ce and other products, allows AppArmor restriction bypass because libcontainer/rootfs_linux.go incorrectly checks mount targets, and thus a malicious Docker image can mount over a <code>/proc</code> directory.
<a href="#">CVE-2018-1277</a>	Cloud Foundry Garden-runc, versions prior to 1.13.0, does not correctly enforce disc quotas for Docker image layers. A remote authenticated user may push an app with a malicious Docker image that will consume more space on a Diego cell than allocated in their quota, potentially causing a DoS against the cell.
<a href="#">CVE-2018-1191</a>	Cloud Foundry Garden-runc, versions prior to 1.11.0, contains an information exposure vulnerability. A user with access to Garden logs may be able to obtain leaked credentials and perform authenticated actions using those credentials.
<a href="#">CVE-2018-11084</a>	Cloud Foundry Garden-runc release, versions prior to 1.16.1, prevents deletion of some app environments based on file attributes. A remote authenticated malicious user may create and delete apps with crafted file attributes to cause a denial of service for new app instances or scaling up of existing apps.
<a href="#">CVE-2016-9962</a>	Runc allowed additional container processes via <code>runc exec</code> to be ptraced by the pid 1 of the container. This allows the main processes of the container, if running as root, to gain access to file-descriptors of these new processes during the initialization and can lead to container escapes or modification of runc state before the process is fully placed inside the container.
<a href="#">CVE-2016-3697</a>	libcontainer/user/user.go in runc before 0.1.0, as used in Docker before 1.11.2, improperly treats a numeric UID as a potential username, which allows local users to gain privileges via a numeric username in the password file in a container.

This fix changes Moby (Docker Engine) behavior such that containers are started with a more typical Linux environment. As a workaround, the entry point of a container can be modified to use a utility like <code>capsh(1)</code> to drop inheritable capabilities prior to the primary process starting.
<a href="#">CVE-2021-43784</a>	runc is a CLI tool for spawning and running containers on Linux according to the OCI specification. In runc, netlink is used internally as a serialization system for specifying the relevant container configuration to the <code>C</code> portion of the code (responsible for the based namespace setup of containers). In all versions of runc prior to 1.0.3, the encoder did not handle the possibility of an integer overflow in the 16-bit length field for the byte array attribute type, meaning that a large enough malicious byte array attribute could result in the length overflowing and the attribute contents being parsed as netlink messages for container configuration. This vulnerability requires the attacker to have some control over the configuration of the container and would allow the attacker to bypass the namespace restrictions of the container by simply adding their own netlink payload which disables all namespaces. The main users impacted are those who allow untrusted images with untrusted configurations to run on their machines (such as with shared cloud infrastructure). runc version 1.0.3 contains a fix for this bug. As a workaround, one may try disallowing untrusted namespace paths from your container. It should be noted that untrusted namespace paths would allow the attacker to disable namespace protections entirely even in the absence of this bug.
<a href="#">CVE-2021-30465</a>	runc before 1.0.0-rc95 allows a Container Filesystem Breakout via Directory Traversal. To exploit the vulnerability, an attacker must be able to create multiple containers with a fairly specific mount configuration. The problem occurs via a symlink-exchange attack that relies on a race condition.
<a href="#">CVE-2021-20182</a>	A privilege escalation flaw was found in openshift4/ose-docker-builder. The build container runs with high privileges using a chrooted environment instead of runc. If an attacker can gain access to this build container, they can potentially utilize the raw devices of the underlying node, such as the network and storage devices, to at least escalate their privileges to that of the cluster admin. The highest threat from this vulnerability is to data confidentiality and integrity as well as system availability.
<a href="#">CVE-2020-14300</a>	The docker packages version docker-1.13.1-108.git4ef4b30.el7 as released for Red Hat Enterprise Linux 7 Extras via RHBA-2020:0053 ( <a href="https://access.redhat.com/errata/RHBA-2020:0053">https://access.redhat.com/errata/RHBA-2020:0053</a> ) included an incorrect version of runc that was missing multiple bug and security fixes. One of the fixes regressed in that update was the fix for CVE-2016-9962, that was previously corrected in the docker packages in Red Hat Enterprise Linux 7 Extras via RHSA-2017:0116 ( <a href="https://access.redhat.com/errata/RHSA-2017:0116">https://access.redhat.com/errata/RHSA-2017:0116</a> ). The CVE-2020-14300 was assigned to this security regression and it is specific to the docker packages produced by Red Hat. The original issue - CVE-2016-9962 - could possibly allow a process inside container to compromise a process entering container namespace and execute arbitrary code outside of the container. This could lead to compromise of the container host or other containers running on the same container host. This issue only affects a single version of Docker, 1.13.1-108.git4ef4b30, shipped in Red Hat Enterprise Linux 7. Both earlier and later versions are not affected.
<a href="#">CVE-2020-14298</a>	The version of docker as released for Red Hat Enterprise Linux 7 Extras via RHBA-2020:0053 advisory included an incorrect version of runc missing the fix for CVE-2019-5736, which was previously fixed via RHSA-2019:0304. This issue could allow a malicious or compromised container to compromise the container host and other containers running on the same host. This issue only affects docker version 1.13.1-108.git4ef4b30.el7, shipped in Red Hat Enterprise Linux 7 Extras. Both earlier and later versions are not affected.
<a href="#">CVE-2019-5736</a>	runc through 1.0-rc6, as used in Docker before 18.09.2 and other products, allows attackers to overwrite the host runc binary (and consequently obtain host root access) by leveraging the ability to execute a command as root within one of these types of containers: (1) a new container with an attacker-controlled image, or (2) an existing container, to which the attacker previously had write access, that can be attached with <code>docker exec</code> . This occurs because of file-descriptor mishandling, related to <code>/proc/self/exe</code> .
<a href="#">CVE-2019-19921</a>	runc through 1.0.0-rc9 has Incorrect Access Control leading to Escalation of Privileges, related to libcontainer/rootfs_linux.go. To exploit this, an attacker must be able to spawn two containers with custom volume-mount configurations, and be able to run custom images. (This vulnerability does not affect Docker due to an implementation detail that happens to block the attack.)
<a href="#">CVE-2019-16884</a>	runc through 1.0.0-rc8, as used in Docker through 19.03.2-ce and other products, allows AppArmor restriction bypass because libcontainer/rootfs_linux.go incorrectly checks mount targets, and thus a malicious Docker image can mount over a <code>/proc</code> directory.
<a href="#">CVE-2018-1277</a>	Cloud Foundry Garden-runc, versions prior to 1.13.0, does not correctly enforce disc quotas for Docker image layers. A remote authenticated user may push an app with a malicious Docker image that will consume more space on a Diego cell than allocated in their quota, potentially causing a DoS against the cell.
<a href="#">CVE-2018-1191</a>	Cloud Foundry Garden-runc, versions prior to 1.11.0, contains an Information exposure vulnerability. A user with access to Garden logs may be able to obtain leaked credentials and perform authenticated actions using those credentials.
<a href="#">CVE-2018-11084</a>	Cloud Foundry Garden-runc release, versions prior to 1.16.1, prevents deletion of some app environments based on file attributes. A remote authenticated malicious user may create and delete apps with crafted file attributes to cause a denial of service for new app instances or scaling up of existing apps.
<a href="#">CVE-2016-9962</a>	Runc allowed additional container processes via <code>runc exec</code> to be ptraced by the pid 1 of the container. This allows the main processes of the container, if running as root, to gain access to file-descriptors of these new processes during the initialization and can lead to container escapes or modification of runc state before the process is fully placed inside the container.
<a href="#">CVE-2016-3697</a>	libcontainer/user/user.go in runc before 0.1.0, as used in Docker before 1.11.2, improperly treats a numeric UID as a potential username, which allows local users to gain privileges via a numeric username in the password file in a container.

# Защита от атак на container runtimes

1. Обновление системных компонент
  - Обязательно,
  - Долго, так как требует перезапуск
2. Использование PolicyEngines
  - Обязательно
  - Придерживайтесь whitelist, минимизируйте blacklist, убирайте ненужное
3. Контроль образа и ресурса в CI/CD
  - Совместно с пунктом выше
  - Сложно, но исключает обход через подготовленный образ
4. SeLinux профиль
  - Только для RedHat based OS
5. Усложнение запуска эксплоита с помощью AppArmor профиля
  - Только Debian based OS
  - Нужно создать профиль под каждый контейнер
6. Следование принципу наименьших привилегий
  - Rootless контейнеры, distroless образы, container specific OS для хоста

# На уровне механизмов Kubernetes

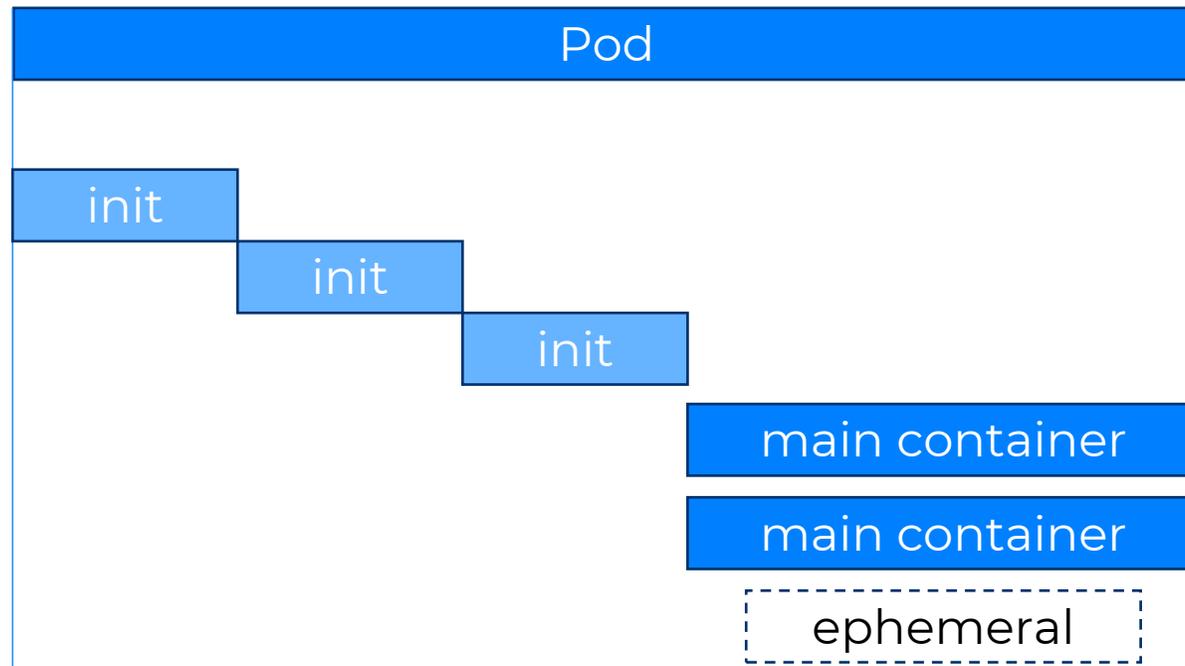

# Жизненный цикл YAML ресурса в k8s

# Типы контейнеров в Pod

Существует **3 типа** контейнеров:

- 1 initContainers
- 2 mainContainers
- 3 ephemeralContainers

# Ephemeral Containers

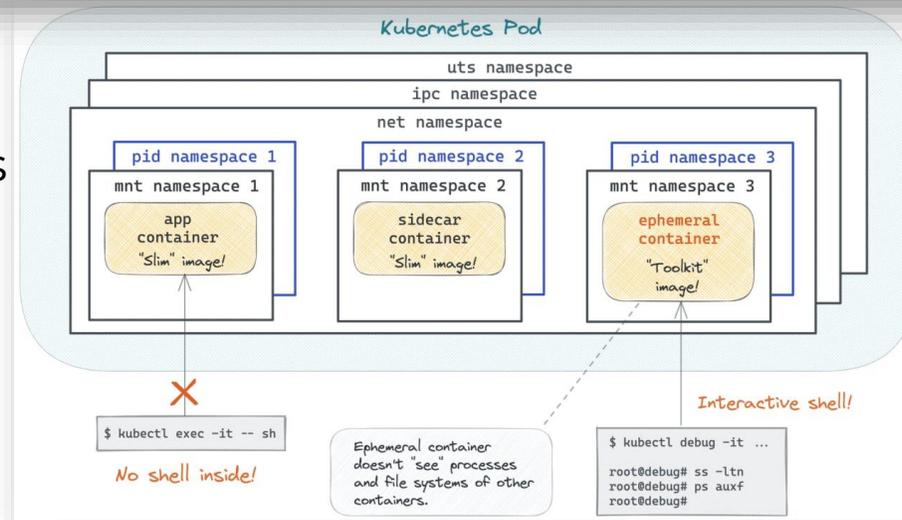

- Появились в 1.18, 1.23 в Beta и включены по умолчанию, в 1.25 в Stable
- Режимы работы:
  - `kubectl debug` в сочетании с `shareProcessNamespace`
  - `kubectl debug` с указанием конкретного container в Pod
  - `kubectl debug` с копированием целевого Pod

`ephemeralContainers`  
`EphemeralContainer` array  
**patch strategy:** merge  
**patch merge key:** name

List of ephemeral containers run in this pod. Ephemeral containers may be run in an existing pod to perform user-initiated actions such as debugging. This list cannot be specified when creating a pod, and it cannot be modified by updating the pod spec. In order to add an ephemeral container to an existing pod, use the pod's `ephemeralcontainers` subresource.

Subresources:

- `pods/ephemeralcontainers`

# Защита от мисконфига и Bad Pods

1. RBAC, соответствующая принципу наименьших привилегий
  - Быстро, надежно, обязательно!
2. Использование PolicyEngine
  - Обязательно!
3. Корректно настроенный ValidatingWebhookConfiguration для PolicyEngine
  - Постоянный контроль конфигурации
3. Принудительный контроль всех типов контейнеров в политиках на Policy Engine
  - Не ограничиваемся PodSecurityStandart – помним про subresources
4. Использование Kubernetes Audit Log
  - Необходима корректно настроенная Audit Policy
5. NetworkPolicy
  - Не все подряд должны ходить в Kubernetes API
  - NetworkPolicy нужно писать ;)
6. Как вариант использование ValidatingAdmissionPolicy
  - Не использует механизм webhook
  - Есть только в последних версиях: 1.26 (alpha), 1.28 (beta), 1.30 (GA)
  - Меньшая гибкость по сравнению с Kyverno и OPA Gatekeeper

**CVE-2024-31989!**

[Источник - Sycode статья "Redis or Not..." - Oreen Livni](#)

# CVE-2024-31989 – Redis – особенности

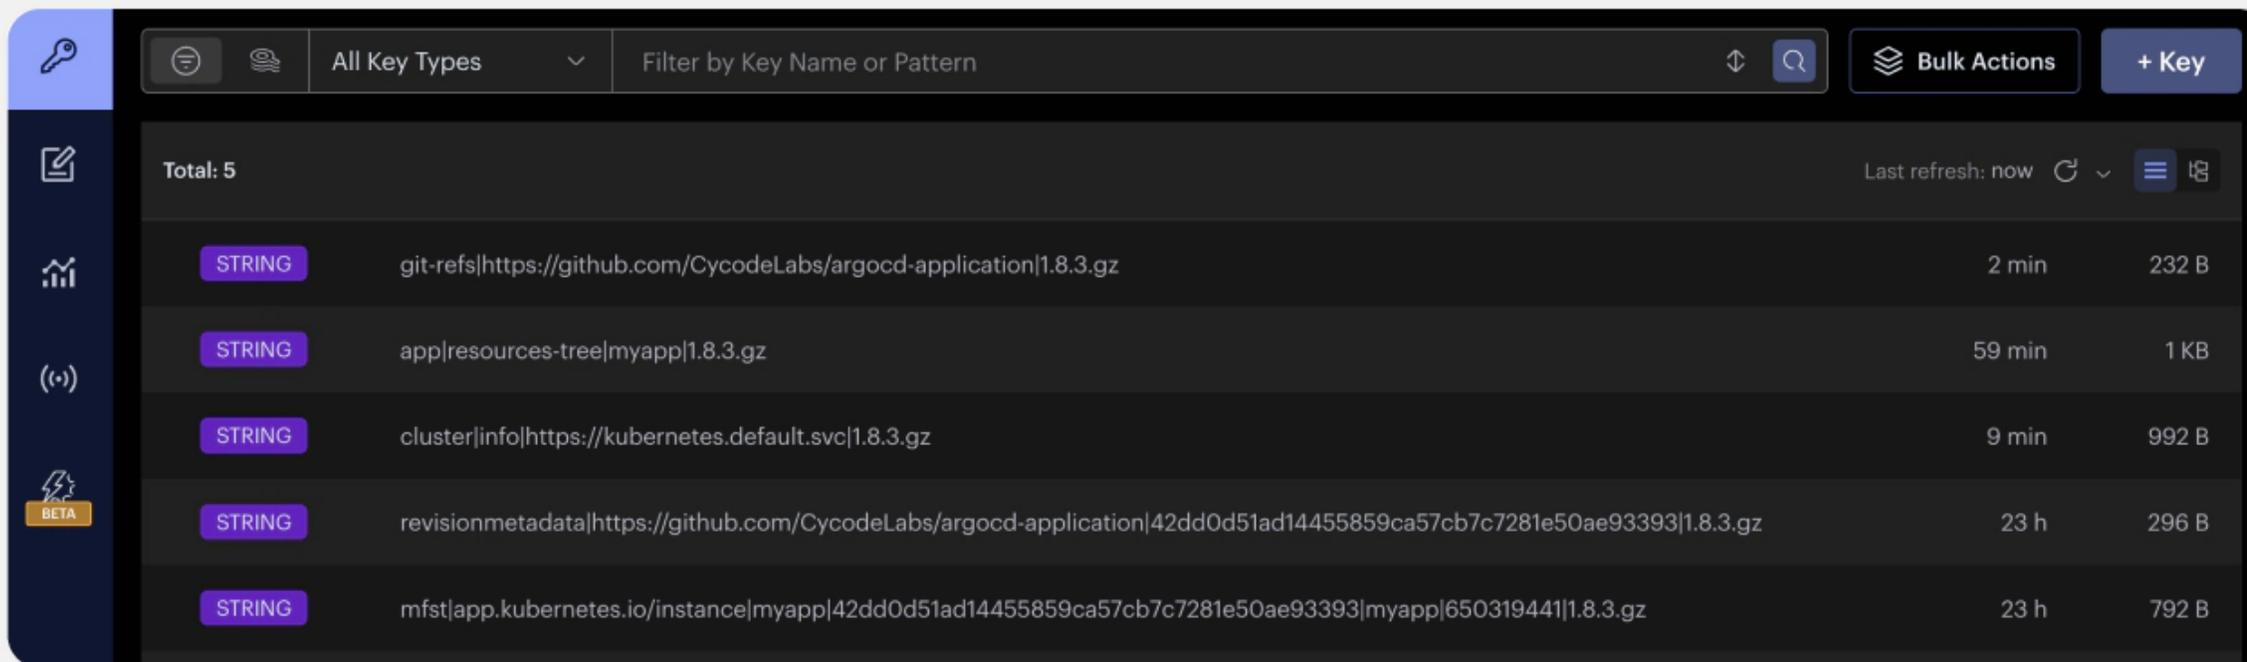

The screenshot shows the Redis Key Explorer interface. At the top, there is a search bar with the text "Filter by Key Name or Pattern" and a search icon. To the right of the search bar are buttons for "Bulk Actions" and "+ Key". Below the search bar, the interface displays a list of keys. The list is titled "Total: 5" and includes a "Last refresh: now" indicator. The keys are listed in a table with columns for key type, key name, TTL, and size.

Key Type	Key Name	TTL	Size
STRING	git-refs https://github.com/CycodeLabs/argocd-application 1.8.3.gz	2 min	232 B
STRING	app resources-tree myapp 1.8.3.gz	59 min	1 KB
STRING	cluster info https://kubernetes.default.svc 1.8.3.gz	9 min	992 B
STRING	revisionmetadata https://github.com/CycodeLabs/argocd-application 42dd0d51ad14455859ca57cb7c7281e50ae93393 1.8.3.gz	23 h	296 B
STRING	mfst app.kubernetes.io/instance myapp 42dd0d51ad14455859ca57cb7c7281e50ae93393 myapp 650319441 1.8.3.gz	23 h	792 B

# CVE-2024-31989 – Redis – особенности

The screenshot shows a Redis key management interface with a list of keys. The interface includes a search bar, a filter dropdown set to 'All Key Types', and a '+ Key' button. The table below shows the details of five keys, including their type (all are STRING), names, last refresh times, and sizes.

Type	Key Name	Last Refresh	Size
STRING	git-refs https://github.com/CycodeLabs/argocd-application 1.8.3.gz	2 min	232 B
STRING	app resources-tree myapp 1.8.3.gz	59 min	1 KB
STRING	cluster info https://kubernetes.default.svc 1.8.3.gz	9 min	992 B
STRING	revisionmetadata https://github.com/CycodeLabs/argocd-application 42dd0d51ad14455859ca57cb7c7281e50ae93393 1.8.3.gz	23 h	296 B

# ArgoCD – проведение атаки

[Источник - Cuscode статья "Redis or Not..." - Oreen Livni](#)

# Защита от подобного

1. Установка обновлений
  - Обязательно
  - Требуется время и перезапуски
2. NetworkPolicy
  - Делаем микросегментацию
  - NetworkPolicy нужно писать ;)
3. Усложнение запуска полезной нагрузки с помощью AppArmor профиля
  - Только Debian based OS
  - Нужно создать профиль под каждый контейнер
4. RBAC
  - Следуем принципу наименьших привилегий. Никаких, ехес!
5. PolicyEngine
  - Никогда не бывает лишним ;)

NO  
FF  
ONE  
2024

# Заключение

# Выводы

1. Уязвимости были, есть и будут!
  - Прописная истина
2. Побег – не всегда и далеко не только “ядерная” история
  - С учетом сложности K8s систем могут быть очень креативные вектора
  - Атаки эволюционируют
3. Обновление
  - Занимаясь патчингом помните, что есть окна, когда вы уязвимы к 1-day
4. Харденинг спасает!
  - Security By Design =)
  - Можно закрыть как 1-day, так и 0-day
5. Знайте и понимайте свою инфраструктуру
  - Нельзя защитить то, что вы не видите и не понимаете
